## Simulation Study

- Error-rate performance without an error-correcting code

- Error-rate performance with outer Turbo code

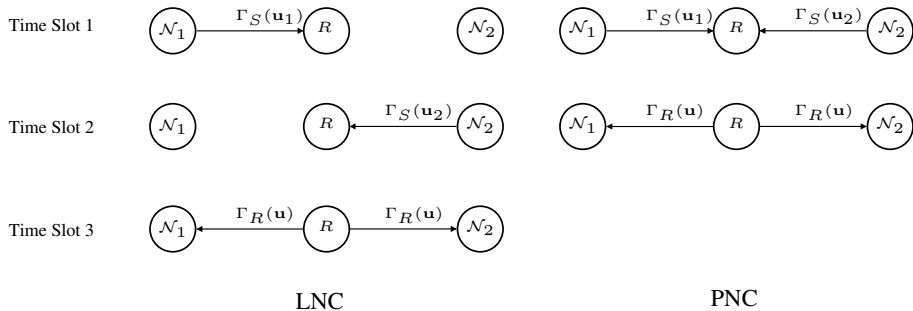

- Throughput comparison - DNC and LNC

## Conclusion

- ▶ *Network coding* is a high-throughput relaying technique which increases throughput over store-and-forward relaying.
- ▶ Network coding may be implemented at the *link* or *physical* layer.
  - ▶ Using *link-layer network coding* (LNC), received symbols are combined after performing demodulation and detection.
  - ▶ Using *physical-layer network coding* (PNC) the network coding is performed on the received sum of electromagnetic signals.
  - ▶ *Digital network coding* (DNC) is an instance of PNC in which the relay performs network coding during demodulation and detection.

Two-way Relay Channel

- ▶ LNC requires three time slots for relaying.
- ▶ PNC only requires two.

- ▶ The primary contribution of this work is a soft-output  $M$ -ary CPFSK demodulator implementing DNC, and a throughput comparison against LNC. Previous work <sup>1</sup> considered binary CPFSK.
- ▶ CPFSK is an attractive modulation for applications in which coherent demodulation is not practical.
- ▶ Simulated error-rate performance is presented for modulation orders 2 and 4.
- ▶ Increasing the modulation order from 2 to 4 provides a higher data rate at the same spectral efficiency, with improved energy efficiency.

Conclusion

Discrete-time system model under DNC operation

- ▶ Considering the MAC phase,
  - ▶ A length- $K$  information sequence is generated at each end node.
  - ▶ When no channel code is applied,
    - ▶ The information sequence is divided into  $K/\mu$  sets of bits, mapped to  $M$ -ary CPFSK symbols, and transmitted to the relay, where  $\mu = \log_2 M$ .
  - ▶ When a channel code is applied,
    - ▶ Identical Turbo channel codes are applied to the information sequences at rate  $r_S$ .
    - ▶ The codeword is divided into  $N_c/\mu$  sets of bits, mapped to  $M$ -ary CPFSK symbols, and transmitted to the relay, where  $\mu = \log_2 M$ .
  
- ▶ Under LNC, the end nodes transmit to the relay in separate time slots, while under DNC, the end nodes transmit simultaneously.
  
- ▶ All channels are modeled as flat-fading channels with independent gains for every signaling interval.
  
- ▶ The broadcast phase contains conventional point-to-point links, and is not analyzed in this work.

# Outline

Introduction

System Model

Digital Network Coding Relay Receiver

Matched Filter Output Distributions

Coherent Reception

Noncoherent Reception with CSI

Noncoherent Reception without CSI

DNC Soft-Demapper

Network Coding Module

Simulation Study

Error-rate performance without an error-correcting code

Throughput comparison - DNC and LNC

Conclusion

- ▶ Consider a single pair of symbols transmitted by the end nodes,  $q_1$  by  $\mathcal{N}_1$  and  $q_2$  by  $\mathcal{N}_2$ , where  $q_1, q_2 \in \{0, \dots, M - 1\}$ .
- ▶ The vector model of the received signal at the relay is

$$\mathbf{y} = h_1 \mathbf{x}_1 + h_2 \mathbf{x}_2 + \mathbf{n}$$

- ▶ where  $h_1 = \alpha_1 e^{j\phi_1}$  and  $h_2 = \alpha_2 e^{j\phi_2}$  are complex-valued channel gains,  $\mathbf{x}_1$  and  $\mathbf{x}_2$  are the vector representations of  $q_1$  and  $q_2$ , and  $\mathbf{n}$  is circularly-symmetric complex Gaussian noise.
- ▶ We desire the expressions:

$$\Lambda(b_k) = \log \left[ \frac{P(b_k = 1 | \mathbf{y})}{P(b_k = 0 | \mathbf{y})} \right], \quad k \in \{0, \dots, \mu - 1\}$$

- ▶ where  $\Lambda(b_k)$  is the log-likelihood ratio of the network coded bit  $b_k = b_{k,1} \oplus b_{k,2}$ , and  $b_{k,1}$  and  $b_{k,2}$ , are the  $k$ -th bit of each symbol.

- ▶ Computation of the log-likelihood ratio of the network coded bit at the relay is broken into three sub-computations,
  - ▶ Probability of the received signal conditioned on the symbols transmitted by the end nodes and channel information.
  - ▶ Probability of the received signal conditioned on the pair of bits mapped to the  $k^{th}$  position of the received symbols.
  - ▶ Log-likelihood ratios of the network-coded bits.

Relay Receiver Block Diagram

- ▶ The pdf of the received signal at the relay under coherent reception is

$$p(\mathbf{y}|\mathbf{m}_{i,j}) = \left(\frac{1}{\pi N_0}\right)^M \exp\left\{-\frac{1}{N_0}\|\mathbf{y} - \mathbf{m}_{i,j}\|^2\right\}$$

- ▶ where the means are defined as

$$\mathbf{m}_{i,j} = h_1\mathbf{x}_1 + h_2\mathbf{x}_2 \quad i, j \in \{0, \dots, M - 1\}$$

- ▶ and the subscripts  $i, j$  denote the transmission of symbol  $q_1 = i$  by  $\mathcal{N}_1$  and  $q_2 = j$  by  $\mathcal{N}_2$ .

- ▶ When the phases of the fading coefficients are unknown at the relay (partial CSI), the conditional pdf of the received signal becomes

$$p(\mathbf{y}|\mu_{i,j}) = \int_0^{2\pi} \int_0^{2\pi} p(\phi_i, \phi_j) p(\mathbf{y}|\mathbf{m}_{i,j}) d\phi_i d\phi_j$$

- ▶ Where  $\mu_{i,j} = |\mathbf{m}_{i,j}|$ , and the phases are uniformly distributed.
- ▶ When the end nodes transmit different tones,

$$p(\mathbf{y}|\mu_{i,j}) = \exp\left\{-\frac{\alpha_1^2 + \alpha_2^2}{N_0}\right\} I_0\left(\frac{2|y_i|\alpha_1}{N_0}\right) I_0\left(\frac{2|y_j|\alpha_2}{N_0}\right)$$

- ▶ When the end nodes transmit the same tone,

$$p(\mathbf{y}|\mu_{i,j}) = \exp\left\{-\frac{\alpha^2}{N_0}\right\} I_0\left(\frac{2|y_i|\alpha}{N_0}\right)$$

- ▶ When the phases and fading amplitudes are not known at the relay (no CSI), and the sources transmit different tones, the conditional pdf of the received signal becomes

$$p(\mathbf{y}|\mathcal{E}_1, \mathcal{E}_2) = \int_0^{2\pi} \int_0^{2\pi} p(\alpha_1, \alpha_2)p(\mathbf{y}|\mu_{i,j})d\alpha_1d\alpha_2$$

- ▶ where  $\mathcal{E}_i$  is the symbol energy utilized at end node  $\mathcal{N}_i$ .
- ▶ And the joint pdf of the fading amplitudes  $\alpha_1, \alpha_2$  is

$$p(\alpha_1, \alpha_2) = \left( \frac{2\alpha_1}{\mathcal{E}_1} \exp \left\{ -\frac{\alpha_1^2}{\mathcal{E}_1} \right\} \right) \left( \frac{2\alpha_2}{\mathcal{E}_2} \exp \left\{ -\frac{\alpha_2^2}{\mathcal{E}_2} \right\} \right)$$

- ▶ When the phases and fading amplitudes are not known at the relay, and the sources transmit the same tones, the conditional pdf of the received signal becomes

$$p(\mathbf{y}|\mathcal{E}_1, \mathcal{E}_2) = \int_0^{2\pi} p(\alpha)p(\mathbf{y}|\mu_{i,j})d\alpha$$

- ▶ And the joint pdf of the fading amplitude  $\alpha$  is

$$p(\alpha) = \frac{2\alpha}{\mathcal{E}_1 + \mathcal{E}_2} \exp \left\{ -\frac{\alpha^2}{\mathcal{E}_1 + \mathcal{E}_2} \right\}$$

- ▶ When the sources transmit the same tone,

$$p(\mathbf{y}|\mathcal{E}_1, \mathcal{E}_2) = \left( \frac{1}{\mathcal{E}_1 + \mathcal{E}_2} \right) \left( \frac{1}{\mathcal{E}_1 + \mathcal{E}_2} + \frac{1}{N_0} \right)^{-1} \exp \left\{ \frac{|y_i|^2 (\mathcal{E}_1 + \mathcal{E}_2)}{N_0^2 + N_0 (\mathcal{E}_1 + \mathcal{E}_2)} \right\}$$

- ▶ When the sources transmit different tones,

$$p(\mathbf{y}|\mathcal{E}_1, \mathcal{E}_2) = \left[ \left( \frac{1}{\mathcal{E}_1 \mathcal{E}_2} \right) \left( \frac{1}{\mathcal{E}_1} + \frac{1}{N_0} \right) \left( \frac{1}{\mathcal{E}_2} + \frac{1}{N_0} \right) \right]^{-1} \exp \left\{ \frac{|y_i|^2 \mathcal{E}_1}{N_0 (N_0 + \mathcal{E}_1)} + \frac{|y_j|^2 \mathcal{E}_2}{N_0 (N_0 + \mathcal{E}_2)} \right\}$$

- ▶ The soft demapper stage computes the probabilities of the received signal conditioned on the  $k^{th}$  bit of the received symbols.
- ▶ The soft mapper takes two inputs,
  1. The set of received signal probabilities conditioned on all possible combinations of received symbols,

$$\{p(\mathbf{y}|q_1, q_2) : (q_1, q_2) \in \mathcal{D} \times \mathcal{D}\}$$

- ▶ where  $\mathcal{D}$  is the set of all possible CPFSK symbols.
- 2. The set of *a-priori* probabilities of the code bits transmitted by the sources, excluding the  $k^{th}$  bit

$$P[\mathbf{b}(q_1) \setminus b_k(q_1)]P[\mathbf{b}(q_2) \setminus b_k(q_2)]$$

- ▶ where the function  $\mathbf{b}(q_i)$  selects all code bits associated with symbol  $q_i$ , and  $b_k(q_i)$  selects the  $k^{th}$  bit associated symbol  $q_i$ .

- ▶ The output of the soft demapper is the set of received signal probabilities conditioned on the bits transmitted by the sources

$$\{p(\mathbf{y}|b_{k,1}, b_{k,2}) : (b_{k,1}, b_{k,2}) \in \mathcal{B} \times \mathcal{B}\}$$

- ▶ where  $\mathcal{B}$  the set of bits  $\{0, 1\}$ .
- ▶ The pdf of the received signal conditioned on the  $k$ -th bit of the received symbols is

$$p(\mathbf{y}|b_{k,1} = m, b_{k,2} = n) = \sum_{\substack{q_1: b_k(q_1)=m \\ q_2: b_k(q_2)=n}} p(\mathbf{y}|q_1, q_2) P[\mathbf{b}_1(q_1) \setminus b_k(q_1)] P[\mathbf{b}_2(q_2) \setminus b_k(q_2)]$$

- ▶ Applying Bayes' rule to the output probabilities of the soft demapper,

$$P(b_{k,1}, b_{k,2} | \mathbf{y}) = \frac{p(\mathbf{y} | b_{k,1}, b_{k,2}) P(b_{k,1}) P(b_{k,2})}{p(\mathbf{y})}$$

$$(b_{k,1}, b_{k,2}) \in \mathcal{B} \times \mathcal{B}$$

- ▶ Denote all possible combinations of bits transmitted by the end nodes as

- ▶  $\mathbb{E}_1 = \{b_{k,1} = 0, b_{k,2} = 0\}$

- ▶  $\mathbb{E}_3 = \{b_{k,1} = 0, b_{k,2} = 1\}$

- ▶  $\mathbb{E}_2 = \{b_{k,1} = 1, b_{k,2} = 1\}$

- ▶  $\mathbb{E}_4 = \{b_{k,1} = 1, b_{k,2} = 0\}$ .

- ▶ The log-likelihood ratio of the network coded bit is then expressed as

$$\Lambda(b_k) = \log \left[ \frac{P(\mathbf{y} | \mathbb{E}_3) P(\mathbb{E}_3) + P(\mathbf{y} | \mathbb{E}_4) P(\mathbb{E}_4)}{P(\mathbf{y} | \mathbb{E}_1) P(\mathbb{E}_1) + P(\mathbf{y} | \mathbb{E}_2) P(\mathbb{E}_2)} \right]$$

Network Coding Module

Simulation Study

Error-rate performance without an error-correcting code

Error-rate performance with outer Turbo code

Throughput comparison - DNC and LNC

Conclusion

- ▶ This section contains simulated error-rate performance at the relay, and end-to-end throughput performance at the end nodes.
- ▶ Error-rate performance is shown for detection of the network-coded bit at the relay
  1. For DNC and LNC.
  2. With and without Turbo channel coding.
  3. For varying levels of channel state information at the relay.
- ▶ In all simulation cases, the end nodes generate frames containing  $K = 4500$  information bits.
- ▶ The throughput of digital and link-layer network coding is compared.

Uncoded error-rate performance at the relay.

Coded error-rate performance at the relay using Turbo code rate  $r_S = 4500/5000$ .

- ▶ The throughput of DNC and LNC is compared by selecting channel code rates which equalize error performance for both systems.
- ▶ The LNC system requires 2 time slots during the MAC phase to transmit  $2K$  information bits to the relay, using length  $N_L = 5000$  code bits at each end node.
- ▶ The DNC system requires a single time slot during the MAC phase to transfer  $2K$  information bits, using length  $N_D$  code bits at each end node.
- ▶ Both systems use  $N_B = 5000$  channel code bits in the broadcast phase.
- ▶ The proportional throughput increase  $T_I$  of DNC over LNC is thus

$$T_I = \frac{2K/(N_D + N_B)}{2K/(2N_L + N_B)} = \frac{15000}{N_D + 5000} \quad (1)$$

Coded error-rate performance used to compare DNC and LNC throughput, assuming no channel state information is available.

Coded error-rate performance used to compare DNC and LNC throughput, assuming partial channel state information is available.

- ▶ The following table summarizes the throughput improvement of DNC over LNC.

<b>Throughput Improvement - <math>T_P</math></b>		
<b>CSI</b>	<b>M=2</b>	<b>M=4</b>
None	30.4%	32.7%
Partial	37.1%	41.0%

Table: Throughput Improvement - DNC over LNC

# Outline

Introduction

Digital Network Coding Relay Receiver

- Matched Filter Output Distributions

  - Coherent Reception

  - Noncoherent Reception with CSI

  - Noncoherent Reception without CSI

- DNC Soft-Demapper

- Network Coding Module

Simulation Study

- Error-rate performance without an error-correcting code

- Error-rate performance with outer Turbo code

- Throughput comparison - DNC and LNC

Conclusion

- ▶ This work presents a soft-output detector which implements DNC in the two-way relay channel.
- ▶ Simulated error-rate and throughput performance for a system which utilizes DNC and LNC, 2 and 4-ary CPFSK modulation, Turbo channel coding, and a fully-interleaved Rayleigh fading channel model.
- ▶ Increasing CPFSK modulation order from 2 to 4 improves DNC energy efficiency by 1 – 2 dB, and decreases the energy efficiency gap between DNC and LNC by 1 dB.
- ▶ DNC increases throughput over LNC by at least 30%, using 2-ary modulation and no channel state information. and by 41%, using 4-ary modulation and partial channel state information.
- ▶ Potential avenues for future work include design of techniques to synchronize the frames transmitted by the end nodes, and implementation in a software radio platform.

Thank You!
