

- Contains the more substituted double bond.
- Favored with an alkoxide base at room temperature or higher.
- Overall the more stable enolate.
- Kinetic Enolate
  - Contains the less substituted double bond.
  - $\circ$   $\,$  Favored with a strong base such as LDA at lower temperatures.
  - The fastest formed, but least stable enolate.

## Halogenation at the Alpha Carbon

• Acidic Conditions

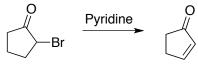

Ph 
$$\xrightarrow{O}$$
  $\xrightarrow{X_2}$   $\xrightarrow{O}$   $X_2 = Cl_2, Br_2, or l_2$ 

- Under acidic conditions, **mono**-halogenation occurs.
- The most commonly used acid is acetic acid (CH<sub>3</sub>COOH), but other acids like HCl and HBr work also.
- o The mechanism of this reaction proceeds via an enol intermediate.
- Basic Conditions

Ph 
$$\xrightarrow{O}$$
  $\xrightarrow{X_2}$   $\xrightarrow{O}$   $\xrightarrow{O}$   $X_2 = Cl_2, Br_2, or l_2$ 

- Under basic conditions, polyhalogenation occurs replacing all of the alpha protons with halogens.
- $\circ$   $\;$  The mechanism of this reaction proceeds via an enolate intermediate.
- Base-Promoted Halogenation of Methyl Ketones (Haloform Reaction)

 Under basic conditions, methyl ketones will get tri-halogenated making this carbon a good leaving group. Hydroxide attacks the carbonyl resulting in the loss of CX<sub>3</sub><sup>-</sup>, which subsequently takes the proton from the RCOOH to yield haloform (HCX<sub>3</sub>). Elimination of Alpha-Halogens to Form α,β-Unsaturated Carbonyl Compounds

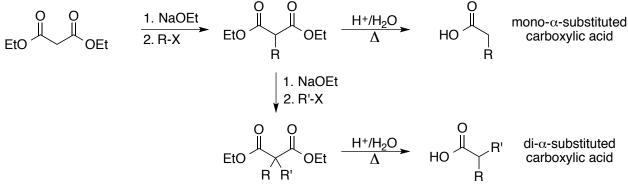

• A halogen  $\alpha$  to a carbonyl can be eliminated using a weak base such as pyridine or Li<sub>2</sub>CO<sub>3</sub>.

**Direct Alpha Carbon Alkylation** 

$$\begin{array}{c}
\text{1. LDA} \\
\text{O} \\
\text{Ph} \\
\begin{array}{c}
\text{THF, -78 °C} \\
\text{2. R-X} \\
\end{array} \\
\begin{array}{c}
\text{O} \\
\text{Ph} \\
\end{array} \\
\begin{array}{c}
\text{Ph} \\
\end{array} \\
\end{array}$$

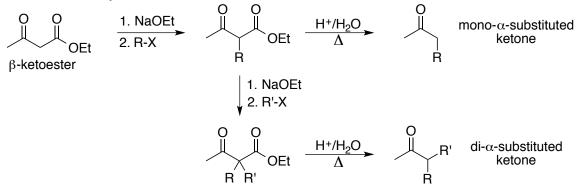

- This reaction allows you to put one or more R-groups on the  $\alpha$ -carbon.
- LDA is the most common base used in the direct alkylation reactions, but alkoxide base can be used if a thermodynamic enolate is desired.
- The alkyl halide used must be methyl or primary because the reaction follows an  $S_{\text{N}}2$  mechanism.

Malonic Ester Synthesis

- Diethyl malonate is the starting material used in this reaction.
- The acidic alpha protons can be substituted by one or two R-groups.
- Hydrolysis and decarboxylation yields an  $\alpha$ -substituted carboxylic acid.

Acetoacetic Ester Synthesis

- This reaction is identical to the malonic ester synthesis except a β-ketoester starting material is used (rather than a diester).
- The product of this reaction is a ketone with one or two R groups at the  $\alpha$ -carbon.
