Some Variants of Satisfiability

We have already encountered several versions of satisfiability problems:

- **intractable:** SAT, 3-SAT
- **tractable:** 2-SAT, HORNSAT

Outline

5. NP-Completeness

- 5.1 Some Variants of Satisfiability
- 5.2 CIRCUIT SAT
- 5.3 NOT-ALL-EQUAL-SAT
- 5.4 1-IN-3-SAT
- 5.5 Some Graph Problems
- 5.6 3-COLORABILITY
- 5.7 HAMILTON-PATH, etc.
- 5.8 Summary

Some Variants of Satisfiability

We have already encountered several versions of satisfiability problems:

- **intractable:** SAT, 3-SAT
- **tractable:** 2-SAT, HORNSAT

We shall encounter further intractable versions of satisfiability problems:

- restricted (but still intractable) versions of **SAT**
- **CIRCUIT SAT**
- **Not-all-equal SAT (NAESAT)**
- **(MONOTONE) 1-IN-3-SAT**
- strongly related problem: **HITTING SET**

Narrowing NP-complete languages

An NP-complete language can sometimes be narrowed down by **transformations** which eliminate certain features of the language but still preserve NP-completeness.

Restricting **SAT** to formulae in CNF and a further restriction to **3-SAT** are typical examples. Generally, **k-SAT** (i.e., formulae are restricted to CNF with exactly k literals in each clause) is NP-complete for any $k \geq 3$.

Proof

The reduction consists in rewriting an arbitrary instance φ of **3-SAT** in such a way that the forbidden features are eliminated.

Consider a variable x appearing $k > 3$ times in φ .

- (i) Replace the first occurrence of x in φ by x_1 , the second by x_2 , and so on where x_1, \dots, x_k are new variables.
- (ii) Add clauses $(\neg x_1 \vee x_2), (\neg x_2 \vee x_3), \dots, (\neg x_{k-1} \vee x_k)$ to φ .

Let φ' be the result of systematically modifying φ in this way. Clearly, φ' has the desired syntactic properties.

Now φ is satisfiable iff φ' is satisfiable:

For each x appearing $k > 3$ times in φ , the truth values of x_1, \dots, x_k are the same in each truth assignment satisfying φ' .

Narrowing NP-complete languages

An NP-complete language can sometimes be narrowed down by **transformations** which eliminate certain features of the language but still preserve NP-completeness.

Restricting **SAT** to formulae in CNF and a further restriction to **3-SAT** are typical examples. Generally, **k-SAT** (i.e., formulae are restricted to CNF with exactly k literals in each clause) is NP-complete for any $k \geq 3$.

Here is another example of narrowing an NP-complete language:

Proposition

3-SAT remains NP-complete even if the Boolean expressions φ in 3-CNF are restricted such that

- each variable appears at most three times in φ and
- each literal appears at most twice in φ .

Boolean Circuits

Syntax of Boolean circuits

- A **Boolean circuit** is a directed graph $C = (V, E)$ where $V = \{1, 2, \dots, n\}$ is the set of gates and C is acyclic (with $i < j$ for all edges $(i, j) \in E$).
- All gates i have a sort $s(i) \in \{\mathbf{true}, \mathbf{false}, \wedge, \vee, \neg\} \cup \{x_1, x_2, \dots\}$.
 - If $s(i) \in \{\mathbf{true}, \mathbf{false}\} \cup \{x_1, x_2, \dots\}$, the indegree of i is 0 (inputs).
 - If $s(i) = \neg$ then the indegree of i is 1.
 - If $s(i) \in \{\vee, \wedge\}$ then the indegree of i is 2.
- Gate n is the output of the circuit.

Remark. $\{x_1, x_2, \dots\}$ are variables whose value can be **true** or **false**.

Boolean Circuits

Semantics

Let C be a Boolean circuit and let $X(C)$ denote the set of variables appearing in the circuit C . A **truth assignment** for C is a function $T : X(C) \rightarrow \{\mathbf{true}, \mathbf{false}\}$.

The **truth value** $T(i)$ for each gate i is defined inductively:

- If $s(i) = \mathbf{true}$, $T(i) = \mathbf{true}$ and if $s(i) = \mathbf{false}$, $T(i) = \mathbf{false}$.
- If $s(i) = x_j \in X(C)$, then $T(i) = T(x_j)$.
- If $s(i) = \neg$, then $T(i) = \mathbf{true}$ if $T(j) = \mathbf{false}$, else $T(i) = \mathbf{false}$ where (j, i) is the unique edge entering i .
- If $s(i) = \wedge$, then $T(i) = \mathbf{true}$ if $T(j) = T(j') = \mathbf{true}$ else $T(i) = \mathbf{false}$ where (j, i) and (j', i) are the two edges entering i .
- If $s(i) = \vee$, then $T(i) = \mathbf{true}$ if $T(j) = \mathbf{true}$ or $T(j') = \mathbf{true}$ else $T(i) = \mathbf{false}$ where (j, i) and (j', i) are the two edges entering i .
- $T(C) = T(n)$, i.e. the **value of the circuit** C .

Proof of NP-Hardness

We prove the NP-hardness by a reduction from **SAT**: Let an arbitrary instance of **SAT** be given by a Boolean formula φ over the variables $X = \{x_1, \dots, x_k\}$. We construct the following Boolean circuit $C(\varphi)$:

- The **variables** $X(C)$ in $C(\varphi)$ are precisely the variables X .
- For every subexpression ψ of φ , $C(\varphi)$ contains a **gate** $g(\psi)$. The **output gate** of $C(\varphi)$ is the gate $g(\varphi)$.
- The **sort and the incoming arcs of each gate** $g(\psi)$ in $C(\varphi)$ are defined inductively:
 - If ψ is a variable x_i then $g(\psi)$ is an input gate of sort $s(g(\psi)) = x_i$.
 - If $\psi = \neg\psi'$ then $s(g(\psi)) = \neg$ with an incoming arc from $g(\psi')$.
 - If $\psi = \psi_1 \wedge \psi_2$ (resp. $\psi = \psi_1 \vee \psi_2$), then $s(g(\psi)) = \wedge$ (resp. $s(g(\psi)) = \vee$) with incoming arcs from $g(\psi_1)$ and $g(\psi_2)$.

CIRCUIT SAT

CIRCUIT SAT

INSTANCE: Boolean circuit C with variables $X(C)$

QUESTION: Does there exist a truth assignment $T : X(C) \rightarrow \{\mathbf{true}, \mathbf{false}\}$ such that $T(C) = \mathbf{true}$?

Theorem

CIRCUIT SAT is NP-complete.

Proof of NP-Membership

Consider the following NP-algorithm:

- 1 Guess a truth assignment $T : X(C) \rightarrow \{\mathbf{true}, \mathbf{false}\}$.
- 2 Check that $T(C) = \mathbf{true}$ holds.

Reduction from SAT to 3-SAT

Motivation

- We have already seen how an arbitrary propositional formula φ can be transformed efficiently into a sat-equivalent formula ψ in 3-CNF.
- This transformation (first into CNF and then into 3-CNF) is intuitive and clearly works in polynomial time. However, the **log-space** complexity of this transformation is not immediate.
- We now give an alternative transformation by reducing **CIRCUIT SAT** to **3-SAT**. In total, we thus have:

$$\mathbf{SAT} \leq_L \mathbf{CIRCUIT SAT} \leq_L \mathbf{3-SAT}$$

Reduction from CIRCUIT SAT to 3-SAT

Let an arbitrary instance of **CIRCUIT SAT** be given by a Boolean circuit C . We construct the following instance $\varphi(C)$ of **SAT** (φ is in CNF with some clauses smaller than 3. The transformation into 3-CNF is obvious):

The formula $\varphi(C)$ uses all variables of C . Moreover, for each gate g of C , $\varphi(C)$ has a new variable g and the following clauses.

- 1 If g is a variable gate x : $(g \vee \neg x), (\neg g \vee x)$. $[g \leftrightarrow x]$
- 2 If g is a **true** (resp. **false**) gate: g (resp. $\neg g$).
- 3 If g is a NOT gate with a predecessor h :
 $(\neg g \vee \neg h), (g \vee h)$. $[g \leftrightarrow \neg h]$
- 4 If g is an AND gate with predecessors h, h' :
 $(\neg g \vee h), (\neg g \vee h'), (g \vee \neg h \vee \neg h')$. $[g \leftrightarrow (h \wedge h')]$
- 5 If g is an OR gate with predecessors h, h' :
 $(\neg g \vee h \vee h'), (g \vee \neg h'), (g \vee \neg h)$. $[g \leftrightarrow (h \vee h')]$
- 6 If g is also the output gate: g .

NAESAT

Proof of NP-Hardness

Recall the Boolean formula $\varphi(C)$ resulting from the reduction of **CIRCUIT SAT** to **3-SAT**. For all one- and two-literal clauses in the resulting CNF-formula $\varphi(C)$, we add the same literal z (possibly twice) to make them 3-literal clauses.

The resulting formula $\varphi_z(C)$ fulfills the following equivalence:

$$\varphi_z(C) \in \mathbf{NAESAT} \Leftrightarrow C \in \mathbf{CIRCUIT SAT}.$$

“ \Rightarrow ” If a truth assignment T satisfies $\varphi_z(C)$ in the sense of **NAESAT**, so does the complementary truth assignment \overline{T} . Thus, z is **false** in either T or \overline{T} which implies that $\varphi(C)$ is satisfied by either T or \overline{T} . Thus C is satisfiable.

NAESAT

Not-all-equal SAT (NAESAT)

INSTANCE: Boolean formula φ in 3-CNF

QUESTION: Does there exist a truth assignment T appropriate to φ , such that the 3 literals in each clause do not have the same truth value?

Remark. Clearly **NAESAT** \subset **3-SAT**.

Theorem

NAESAT is NP-complete.

NAESAT

Proof of NP-Hardness (continued)

“ \Leftarrow ” If C is satisfiable, then there is a truth assignment T satisfying $\varphi(C)$. Let us then extend T for $\varphi_z(C)$ by assigning $T(z) = \mathbf{false}$.

By assumption, T is a satisfying truth assignment of $\varphi(C)$ and, therefore, also of $\varphi_z(C)$. Hence, in no clause of $\varphi_z(C)$ all literals are **false**. It remains to show that in no clause of $\varphi_z(C)$ all literals are **true**:

- (i) Clauses for **true/false**/NOT/variable gates contain z that is **false**.
- (ii) For AND gates the clauses are: $(\neg g \vee h \vee z), (\neg g \vee h' \vee z), (g \vee \neg h \vee \neg h')$ where in the first two z is **false**, and in the third all three cannot be **true** as then the first two clauses would be **false**.
- (iii) For OR gates the clauses are: $(\neg g \vee h \vee h'), (g \vee \neg h' \vee z), (g \vee \neg h \vee z)$ where in the last two z is **false**, and in the first all three cannot be **true** as then the last two clauses would be **false**.

1-IN-3-SAT

1-IN-3-SAT

INSTANCE: Boolean formula φ in 3-CNF

QUESTION: Does there exist a truth assignment T appropriate to φ , such that in each clause, exactly one literal is **true** in T ?

MONOTONE 1-IN-3-SAT

INSTANCE: Boolean formula φ in 3-CNF, s.t. the clauses in φ contain only unnegated atoms.

QUESTION: Does there exist a truth assignment T appropriate to φ , such that in each clause, exactly one literal is **true** in T ?

Theorem

Both **1-IN-3-SAT** and **MONOTONE 1-IN-3-SAT** are NP-complete.

Proof of the NP-hardness of 1-IN-3-SAT

We prove the NP-hardness by a reduction from **4-SAT**:

Let φ be an arbitrary instance of **4-SAT**, i.e., φ is in 4-CNF.

We construct an instance ψ of **1-IN-3-SAT** as follows:

For every clause $l_1 \vee l_2 \vee l_3 \vee l_4$ in φ , let $a_1, a_2, a_3, a_4, b_1, b_2, c_1, c_2, d$ be 9 fresh propositional variables. Then ψ contains the following 7 clauses:

- | | | |
|-----------------------------|-----------------------------|---------------------------|
| (1) $l_1 \vee a_1 \vee b_1$ | (4) $l_3 \vee a_3 \vee b_2$ | |
| (2) $l_2 \vee a_2 \vee b_1$ | (5) $l_4 \vee a_4 \vee b_2$ | (7) $b_1 \vee b_2 \vee d$ |
| (3) $a_1 \vee a_2 \vee c_1$ | (6) $a_3 \vee a_4 \vee c_2$ | |

Idea. Suppose that in a truth assignment T of φ all literals in the clause $l_1 \vee \dots \vee l_4$ are **false**:

By (1) – (3): If l_1 and l_2 are **false**, then b_1 must be **true**.

By (4) – (6): If l_3 and l_4 are **false**, then b_2 must be **true**.

However, by (7), it is not allowed that both b_1 and b_2 are **true**.

1-IN-3-SAT

Remarks

- Clearly **1-IN-3-SAT** \subset **NAESAT** \subset **3-SAT**. The **instances** of these 3 problems are the same, namely 3-CNF formulae. However, the **positive instances** of **1-IN-3-SAT** are a proper subset of **NAESAT**, which in turn are a proper subset of the positive instances of **3-SAT**.
- Note that the NP-completeness of any of these 3 problems does not immediately imply the NP-completeness of any of the other problems, since it is a priori not clear if further constraining the positive instances makes things easier or harder.
- MONOTONE 1-IN-3-SAT** is a special case of **1-IN-3-SAT**, i.e., the **instances** of the former are a proper subset of the latter while the question remains the same. The NP-hardness of the special case immediately implies the NP-hardness of the general case.

Proof of the NP-hardness of MONOTONE 1-IN-3-SAT

We show how an arbitrary instance φ of **1-IN-3-SAT** can be transformed into an equivalent instance ψ of **MONOTONE 1-IN-3-SAT**:

Let $X = \{x_1, \dots, x_n\}$ be the variables in φ . Then the variables in ψ are $X \cup \{x'_i \mid 1 \leq i \leq n\} \cup \{a, b, c\}$. In φ , we **replace every negative literal** of the form $\neg x_i$ (for some i) by the unnegated atom x'_i .

Moreover, for every $i \in \{1, \dots, n\}$, we **add the following 3 clauses**:

- (1) $x_i \vee x'_i \vee a$
- (2) $x_i \vee x'_i \vee b$
- (3) $a \vee b \vee c$

Idea. These three clauses guarantee that in a legal 1-in-3 assignment of ψ , the variables x_i and x'_i have complementary truth values. Hence, x'_i indeed encodes $\neg x_i$.

HITTING SET

HITTING SET

INSTANCE: Set $T = \{t_1, \dots, t_p\}$, family $(V_i)_{1 \leq i \leq n}$ of subsets of T , i.e.: for all $i \in \{1, \dots, n\}$, $V_i \subseteq T$.

QUESTION: Does there exist a set $W \subseteq T$, s.t. $|W \cap V_i| = 1$ for all $i \in \{1, \dots, n\}$? (A set W with this property is called a "hitting set").

Corollary

HITTING SET is NP-complete.

Proof of the NP-hardness

By reduction from **MONOTONE 1-IN-3-SAT**: Let an instance of **MONOTONE 1-IN-3-SAT** be given by the 3-CNF formula φ over the variables X . We define the following instance of **HITTING SET**:

$T = X$. Moreover, suppose that φ contains n clauses. Then there are n sets $(V_i)_{1 \leq i \leq n}$. If the i -th clause in φ is $l_1 \vee l_2 \vee l_3$, then $V_i = \{l_1, l_2, l_3\}$.

INDEPENDENT SET

INSTANCE: Undirected graph $G = (V, E)$ and integer K .

QUESTION: Does there exist an *independent set* I of size $\geq K$? i.e., $I \subseteq V$, s.t. for all $i, j \in I$ with $i \neq j$, $[i, j] \notin E$.

CLIQUE

INSTANCE: Undirected graph $G = (V, E)$ and integer K .

QUESTION: Does there exist a *clique* C of size $\geq K$? i.e., $C \subseteq V$, s.t. for all $i, j \in C$ with $i \neq j$, $[i, j] \in E$.

VERTEX COVER

INSTANCE: Undirected graph $G = (V, E)$ and integer K .

QUESTION: Does there exist a *vertex cover* N of size $\leq K$? i.e., $N \subseteq V$, s.t. for all $[i, j] \in E$, either $i \in N$ or $j \in N$.

Some Graph Problems

We have already proved the NP-completeness of the following graph problems:

- **INDEPENDENT SET**
- **CLIQUE**
- **VERTEX COVER**

We shall now show the following results:

- **3-COLORABILITY** is NP-complete.
- **HAMILTON-PATH** \leq_L **HAMILTON-CYCLE** \leq_L **TSP(D)**

Decision Problems

3-COLORABILITY

INSTANCE: Undirected graph $G = (V, E)$

QUESTION: Does G have a *3-coloring*? i.e., an assignment of one of 3 colors to each of the vertices in V such that any two vertices i, j connected by an edge $[i, j] \in E$ do not have the same color?

k-COLORABILITY (for fixed value k)

INSTANCE: Undirected graph $G = (V, E)$

QUESTION: Does G have a *k-coloring*? i.e., an assignment of one of k colors to each of the vertices in V such that any two vertices i, j connected by an edge $[i, j] \in E$ do not have the same color?

Complexity

Theorem

The **k-COLORABILITY**-problem is NP-complete for any fixed $k \geq 3$.
The **2-COLORABILITY**-problem is in P.

Proof

NP-Membership of k-COLORABILITY:

1. Guess an assignment $f : V \rightarrow \{1, \dots, k\}$
2. Check for every edge $[i, j] \in E$ that $f(i) \neq f(j)$.

P-Membership of 2-COLORABILITY: (w.l.o.g., G is connected)

1. Start by assigning an arbitrary color to an arbitrary vertex $v \in V$.
2. Suppose that the vertices in $S \subset V$ have already been assigned a color. Choose $x \in S$ and assign to all vertices adjacent to x the opposite color. G is 2-colorable iff step 2 never leads to a contradiction.

Example

The 3-CNF formula $\varphi = (x_1 \vee \neg x_2 \vee x_3) \wedge (x_2 \vee x_3 \vee \neg x_4)$ is reduced to the following graph:

NP-Hardness Proof of 3-COLORABILITY

By reduction from **NAESAT**: Let an arbitrary instance of **NAESAT** be given by a Boolean formula $\varphi = c_1 \wedge \dots \wedge c_m$ in 3-CNF with variables x_1, \dots, x_n . We construct the following graph $G(\varphi)$:

Let $V = \{a\} \cup \{x_i, \neg x_i \mid 1 \leq i \leq n\} \cup \{l_{ij}, l_{i2}, l_{i3} \mid 1 \leq i \leq m\}$,
i.e. $|V| = 1 + 2n + 3m$.

For each variable x_i in φ , we introduce a triangle $[a, x_i, \neg x_i]$,
i.e. all these triangles share the node a .

For each clause c_i in φ , we introduce a triangle $[l_{i1}, l_{i2}, l_{i3}]$. Moreover,
each of these vertices l_{ij} is further connected to the node corresponding
to this literal, i.e.: if the j -th literal in c_i is of the form x_α (resp. $\neg x_\alpha$)
then we introduce an edge between l_{ij} and x_α (resp. $\neg x_\alpha$).

Example

The 3-CNF formula $\varphi = (x_1 \vee \neg x_2 \vee x_3) \wedge (x_2 \vee x_3 \vee \neg x_4)$ is reduced to the following graph:

Let red = **false** and green = **true**. The above 3-coloring corresponds to
 $T(x_1) = T(\neg x_2) = T(\neg x_3) = T(\neg x_4) = \text{true}$.

Correctness of the Problem Reduction

Proof (continued)

“ \Leftarrow ” Suppose that G has a 3-coloring with colors $\{0, 1, 2\}$. W.l.o.g., the node a has the color 2. This induces a truth assignment T via the colors of the nodes x_i : if the color is 1, then $T(x_i) = \mathbf{true}$ else $T(x_i) = \mathbf{false}$. We claim that T is a legal **NAESAT**-assignment. Indeed, if in some clause, all literals had the value **false** (resp. **true**), then we could not use the color 0 (resp. 1) for coloring the triangle $[l_{i1}, l_{i2}, l_{i3}]$, a contradiction.

“ \Rightarrow ” Suppose that there exists an **NAESAT**-assignment T of φ . Then we can extract a 3-coloring for G from T as follows:

- (i) Node a is colored with color 2.
- (ii) If $T(x_i) = \mathbf{true}$, then color x_i with 1 and $\neg x_i$ with 0 else vice versa.
- (iii) From each $[l_{i1}, l_{i2}, l_{i3}]$, color two literals having opposite truth values with 0 (**true**) and 1 (**false**). Color the third with 2.

Complexity

Theorem

HAMILTON-PATH, **HAMILTON-CYCLE**, and **TSP(D)** are NP-complete.

Proof

We shall show the following chain of reductions:

$$\mathbf{HAMILTON-PATH} \leq_L \mathbf{HAMILTON-CYCLE} \leq_L \mathbf{TSP(D)}$$

It suffices to show **NP-membership** for the *hardest* problem:

1. Guess a tour π through the n cities.
2. Check that $\sum_{i=1}^n d_{\pi(i)\pi(i+1)} \leq B$ with $\pi(n+1) = \pi(1)$.

Likewise, it suffices to prove the **NP-hardness** of the *easiest* problem.

The NP-hardness of **HAMILTON-PATH** (by a reduction from **3-SAT**) is quite involved and is therefore omitted here (see Papadimitriou's book).

HAMILTON-PATH

INSTANCE: (directed or undirected) graph $G = (V, E)$

QUESTION: Does G have a *Hamilton path*?
i.e., a path visiting all vertices of G exactly once.

HAMILTON-CYCLE

INSTANCE: (directed or undirected) graph $G = (V, E)$

QUESTION: Does G have a *Hamilton cycle*?
i.e., a cycle visiting all vertices of G exactly once.

TSP(D)

INSTANCE: n cities $1, \dots, n$ and a nonnegative integer distance d_{ij} between any two cities i and j (such that $d_{ij} = d_{ji}$), and an integer B .

QUESTION: Is there a tour through all cities of length at most B ?
i.e., a permutation π s.t. $\sum_{i=1}^n d_{\pi(i)\pi(i+1)} \leq B$ with $\pi(n+1) = \pi(1)$.

HAMILTON-PATH vs. HAMILTON-CYCLE

HAMILTON-PATH \leq_L HAMILTON-CYCLE

(We only consider undirected graphs). Let an arbitrary instance of **HAMILTON-PATH** be given by the graph $G = (V, E)$. We construct an equivalent instance $G' = (V', E')$ of **HAMILTON-CYCLE** as follows:

Let $V' := V \cup \{z\}$ for some new vertex z and $E' := E \cup \{[v, z] \mid v \in V\}$.
 G has a Hamilton path $\Leftrightarrow G'$ has a Hamilton cycle

“ \Rightarrow ” Suppose that G has a Hamilton path π starting at vertex a and ending at b . Then $\pi \cup \{z\}$ is clearly a Hamilton cycle in G' .

“ \Leftarrow ” Let C be a Hamilton cycle in G' . In particular, C goes through z . Let a and b be the two neighboring nodes of z in this cycle. Then $C \setminus \{z\}$ is a Hamilton path (starting at vertex a and ending at b) in G .

HAMILTON-CYCLE vs. TSP(D)

HAMILTON-CYCLE \leq_L TSP(D)

Let an arbitrary instance of **HAMILTON-CYCLE** be given by the graph $G = (V, E)$. We construct an equivalent instance of **TSP(D)** as follows:

Let $V = \{1, \dots, n\}$. Then our instance of **TSP(D)** has n cities.

Moreover, for any two cities $i \neq j$, the distance is defined as

$$d_{ij} = \begin{cases} 1 & \text{if } [i, j] \in E \\ 2 & \text{otherwise} \end{cases}$$

Finally, we set $B = n$.

Clearly, there is no tour through all cities of length $< B = n$.

Moreover, the Hamilton cycles in G are precisely the tours of length B .

Hence, G has a Hamilton cycle \Leftrightarrow there exists a tour of length $\leq B$.

Learning Objectives

- The concept of NP-completeness and its characterizations in terms of succinct certificates.
- You should now be familiar with the intuition of NP-completeness (and recognize NP-complete problems)
- Basic techniques to prove problems NP-complete
- A basic repertoire of NP-complete problems (in particular, versions of **SAT** and some graph problems) to be used in further NP-completeness proofs.
- Reductions, reductions, reductions, ...

Summary of Reductions
